

## Interface Products

#### • Analog/Digital Converters

It is frequency required to record analog information, such as temperature, pressure, battery level, signal strength, etc. The analog voltage information from the diode, pressure sensor, transducer, etc., needs to be converted to digital 1s and 0s (ADC) so that the information can be processed by a microcontroller and subsequently displayed, used to control contracts, switches, relay, etc. Conversion from digital 1s and 0s to analog voltages (DAC) is also useful for applications like LCD contrast control. I<sup>2</sup>C/SMBus ADC and DAC devices provide an easy way to convert between digital and analog signals and send the information via the I<sup>2</sup>C/SMBus.

#### • Bus Controllers

The bus controller serves as an interface between most standard parallel-bus microcontrollers/microprocessors and the serial I<sup>2</sup>C bus, and allows the parallel bus system to communicate bi-directionally with the I<sup>2</sup>C bus. This is commonly referred to as the bus master. Communication with the I<sup>2</sup>C bus is carried out on a byte-wise basis using interrupt or polled handshake and controls all of the I<sup>2</sup>C bus specific sequences, protocol, arbitration, and timing.

#### • Hardware Monitors

Temperature measurement is a vital part of several industrial and automotive applications. Thermal monitoring and controlling are important for high-speed microprocessors as well. Philips Semiconductors designs, manufactures, and markets a wide number of temperature sensors that support a variety of applications in the consumer, industrial, and PC markets. Our temperature sensors are subdivided into two major groups: general and PC applications. The choice of temperature sensor depends on the temperature range and other selection criteria to match the device to the particular system needs.

#### • LED Blinkers

The LED Blinkers blink LEDs in I<sup>2</sup>C and SMBus applications where it is necessary to limit bus traffic or free up the I<sup>2</sup>C Master (MCU, MPU, DSP, chipset, etc.) timer. The uniqueness of these devices is the internal oscillator accurate to  $\pm 10\%$  with two programmable blink rates adjustable between 40 Hz and 6.4 seconds.

To blink LEDs using normal I/O Expanders like the PCF8574 or PCA9554, the bus master must send repeated commands to turn the LED on and off. This greatly increases the amount of traffic on the I<sup>2</sup>C bus and uses up one of the master's timers. The PCA9550, PCA9551, PCA9552, and PCA9553 LED Blinkers instead require only the initial set up command to program the frequency and duty cycle (i.e., blink rate) for each individual port BLINK RATE 1 and BLINK RATE 2. From then on, it only requires one command from the bus master to turn the individual LEDs ON, OFF, or to blink at BLINK RATE 1 or BLINK RATE 2.

The LED Blinkers can also be used to dim LEDs (e.g., for back-lights) by running at the maximum blink rate and then varying duty cycle between 1 and 100%.

Any bits not used for controlling the LEDs can be used for General Purpose Parallel Input/Output (GPIO) expansion. I/O expansion provides a simple solution when additional I/O is needed for ACPI power switches, sensors, pushbuttons, alarm monitoring, fans, etc.

#### • Dip Switches

I<sup>2</sup>C commands and/or hardware pins are used to select between the default values or the setting programmed from the I<sup>2</sup>C bus and stored in the onboard I<sup>2</sup>C EEPROM register. These onboard values can be changed at any time via the I<sup>2</sup>C bus. The non-volatile I<sup>2</sup>C EEPROM register values stay resident even when the device is powered down. The device powers up with either the hardware pin inputs or the EEPROM retained value on the hardware output pins depending on the position (H or L) of the MUX select pins. The EEPROMs have 10-year memory retention and are rated for 3000 write cycles in the data sheet but have been tested to 50,000 cycles with no failures.

#### • Repeaters/Hubs/Expanders

New bus buffers from Philips Semiconductors overcome the previous system capacitance limitation of 400pF. These new bus buffers allow designers more freedom in their design to expand the use of the I<sup>2</sup>C or SMBus:

- More I<sup>2</sup>C devices than the 400pF maximum allowed by the I<sup>2</sup>C specification
- Long bus wiring in point-to-point or multi-point applications
- Different operating supply voltages or logic voltage levels within one system
- Opto-isolation for safety or due to difference in ground plane
- Isolating a section of a system that has lost its power supply
- Insertion of unpowered cards into an active I<sup>2</sup>C bus on multi-point backplanes like those found in CompactPCI, VME, or AdvancedTCA systems

#### • Multiplexers/Switches

Our Philips multiplexers and switches are bi-directional translating switches that are controlled by an I<sup>2</sup>C or SMBus. They fan-out an upstream SCL/SDA pair to either 2, 4, or 8 downstream channels of SCx/SDx pairs.

The multiplexers allow only one downstream channel to be selected at a time while the switches allow any individual downstream channel or combination of downstream channels to be selected.

The selection depends on the contents of a programmable control register. Once one or several channels have been selected, the device acts as a wire, allowing the master on the upstream channel to send commands to devices on all the active downstream channels. Devices on the active downstream channels can communicate with each other and the master. External pull-up resistors are used to pull each individual channel up to the desired voltage level.

#### • Serial EEPROMs

Small size serial memories (RAM and EEPROM) are fairly common and widely used in many different applications. EEPROMs are particularly useful in applications where data retention during power-off is essential. Such applications include, but are not limited to, meter readings, electronic key, product identification number, and Serial Presence Detect (SPD) on DIMMs. A common pinning is used for these serial memories because their functionality is very similar. The common pinout was selected to allow interchangeability.

EEPROMs store data (2Kbits organized in 256 X 8 in the PCF8582C-2 for example), such as set points, temperature, alarms, and DIMM information for a guaranteed minimum storage time of ten years in the absence of power. EEPROMs can change values up to 1,000,000 times and have an infinite number of read cycles, while consuming only 10 micro amperes of current.

Device Type	Supply voltage V	f <sub>MAX</sub> MHz	Inputs number x type	Outputs number x type	Skew output-output ps		Skew part-part ps	Rise/fall time ps	Operating temperature °C	Other features	Packages	Intended application

## 16Cxxx UARTs Product Overview

## Why choose Philips Semiconductors?

### Features

- \* Broad portfolio of single, dual and quad UARTs
- \* All devices operate at 2.5V, 3.3V and 5V and are specified at industrial temperature range (-40 to +85°C)
- \* Fastest bus cycle times in the industry
- \* Power down mode
- \* Supports IRDA feature
- \* Shareware for programming readily available
- \* Automatic hardware and software flow control
- \* Supports DMA mode and includes a wide variety of FIFO depth
- \* Pin to pin compatible with existing 16C devices

### Benefits

- \* One stop shopping for various applications
- \* One part fits multiple needs/applications (lowers the cost of inventory, compared to competitor solutions)
- \* Shortens design cycle
- \* DMA and deep FIFOs reduce CPU overhead
- \* Compatibility with high speed processors
- \* Ideal for battery operated systems
- \* Allows wireless short range applications
- \* Alternate source to other manufacturers

## Industrial UARTs Product Overview

## Why choose Philips Semiconductors?

## Features

- \* Broad line of UARTs from single to octals
- \* Power down mode
- \* Extensive interrupt support
- \* Hardware RS485/Multidrop support
- \* Automatic outband flow control
- \* All receivers and transmitters are fully independent with respect to speed and clock frequency
- \* Flexible and programmable I/O structure

## Benefits

- \* Many choices for various applications
- \* Ideal for low power consumption
- \* Reduced software overhead
- \* Reduction of CPU overhead
- \* Avoids loss of data
- \* Transmit and receive channel can operate at different baud rates
- \* Allows usage of I/O pins for general purposes

**Why choose Philips Semiconductors?**

#### Benefits

- \* Only two bus lines are required: a serial data line (SDA) and a serial clock line (SCL)
- \* Each device connected to the bus is software-addressable through a unique address and simple master/slave relationship exist at all times. Masters can operate as master-transmitters or as master-receivers
- \* True multi-master bus operation, including collision detection and arbitration to prevent data corruption if two or more masters simultaneously initiate data transceivers
- \* Serial, 8-bit oriented, bi-directional data transfers can be made at 100 kbit/s in the standard mode or 400 kbit/s in the fast mode.
- \* On-chip filtering (50 ns) rejects spikes on the bus data line to preserve data integrity
- \* The number of ICs that can be connected to the same bus is limited only by a maximum bus capacitance of 400 pF
